

$$\begin{aligned} a &= f(b, c, d) \\ b &= f(c, d) \\ \dot{d} &= f(a) \end{aligned}$$

Model Logics

The model is a list of equations linking fields together

Dependency graph

order is found when no circularity for state variables

$[b, a]$
 $[d]$

Resolution order

Space allocation

parallel and region are common to all fields. Agents and coupling size are field-dependant

Initial values

statevar are deduced from parameter and initial differential values

Temporal solver

Parallel systems never interacts. Between two fields *agents* and *coupling* dimensions must match.
